

DEMO SETUP GUIDE

How to install, launch, and demonstrate Qudra on a separate computer.

This guide is intended for a controlled demonstration using the project's example data. The demo account switcher is not production authentication. Do not expose the demo instance publicly or use real personal data.

Repository: <https://github.com/heshamYehya19/WASL>

Brand: Qudra (■■■■) — “ability” or “capability”.

1. What you need

Install these tools on the demo computer:

- Git — to download the repository.
- Node.js 22.18 or newer (Node.js 24 LTS is a suitable option).
- npm — included with Node.js.
- A modern browser such as Chrome or Edge.

Check the installations in Terminal, PowerShell, or Command Prompt:

```
git --version
node --version
npm --version
```

The Node.js version must be at least 22.18.0.

2. Download the project

Open a terminal and run:

```
git clone https://github.com/heshamYehya19/WASL.git
cd WASL
```

If the repository has been renamed or moved, use the repository URL supplied by the project owner.

3. Install dependencies

```
npm install
```

Wait for installation to finish. If this command fails, resolve the error before continuing.

4. Configure AI (only if live AI features are needed)

The application may start with its seeded example data without an API key, but some AI-powered actions may require a valid provider key.

1. Find `.env.example` in the project root.
2. Copy it to a new file named `.env`.
3. Follow the variable names and instructions in `.env.example`.
4. Add your own valid provider key only to the appropriate local variable.
5. Save the file and restart the server after changing environment variables.

Never commit or share `.env`, and never paste API keys into this guide, slides, screenshots, or chat messages. Use `.env.example` as the source of truth for exact variable names.

Without a working provider key, AI-dependent assessments may be unavailable or use configured fallback/template behavior. Do not present fallback output as a successful live AI assessment.

5. Start the demo

Recommended: run locally on the demo computer

```
npm run dev -- --port 5174 --strictPort
```

Keep the terminal open while using the site. Open this address in a browser on the same computer:

`http://localhost:5174`

If the terminal reports that the port is already in use, stop the other process using it or choose another available port and use the URL printed by the server.

Optional: production build

```
npm run build  
npm start
```

If the repository has an npm start script and the build succeeds, open **<http://localhost:3000>**.

6. Demo data and account switching

The demo includes seeded example data. The local SQLite database is documented in the current project as `data/wasl.db`. Some internal paths and names may still say WASL; these are implementation details, not the user-facing brand.

Profile	Demo identifier	Suggested use
Nahla Systems	co-nahla	Company-side challenge and talent workflow
Orbit Analytics	co-orbit	Alternate company view
Sara Nasser	cand-sara	Candidate with a mostly fresh/empty progress view
Layla Haddad	cand-layla	Candidate example with phases completed
Omar Saleh	cand-omar	Candidate example with early-phase progress

Use the account switcher inside the website. Do not manually edit browser storage or request headers during the presentation.

Security note

The account switcher is a demo identity mechanism, not real authentication. It does not provide production-grade password-based sign-in or session security. Run the demo only in a controlled environment and do not use real candidate data.

7. Resetting the demo

Use the application's own reset controls if available. A database reset may also be available through:

```
npm run db:reset
```

Warning: resetting the database can erase local demo changes. Stop the running server first if required by the reset script. Restart the server and verify the seeded examples before presenting. Do not manually delete the database unless you understand the initialization behavior.

8. Suggested demo walkthrough

1. Start on the company side: select Nahla Systems (co-nahla) and show the structured, phased challenge workflow.
2. Switch to a candidate profile and explain how candidates demonstrate skills through work, not just a résumé.
3. Use Layla Haddad to show completed phases, or Omar Saleh to show earlier progress.
4. Explain that AI-assisted review supports assessment while defined application rules determine progression and completion.
5. Show how candidate evidence can help employers evaluate skills relevant to a challenge.

Use only features you have personally verified on the demo computer.

9. Troubleshooting

“node” or “npm” is not recognized

Install Node.js 22.18 or newer, close and reopen the terminal, then repeat the version checks.

Dependencies fail to install

Check the Node version and internet access, then retry `npm install`. Do not delete the lockfile as a first troubleshooting step.

The website does not open

Make sure the server is still running and use the exact URL printed by the terminal. For the recommended command, use `http://localhost:5174`.

Demo data is missing

Confirm that the application initialized its SQLite database and that seeding is enabled according to the project instructions. Inspect the reset/seed scripts before changing database files.

AI assessment is unavailable

Check the provider key using the variable names in `.env.example`, then restart the server. Provider availability, account limits, network access, and API quota can affect live AI calls. Do not depend on untested live AI during the presentation.

A previous presenter changed the data

Use the in-app reset controls or the documented database reset script, then relaunch and verify the intended profiles.

10. Pre-demo checklist

- Node.js version is 22.18 or newer.
- `npm install` completed successfully.
- The website opens on the demo computer.
- Qudra branding and both theme modes look correct.
- Seeded company and candidate profiles are available.
- The presenter has rehearsed every account switch and click path.
- AI-dependent actions were tested, or the demo avoids relying on unverified live AI.
- No API keys or `.env` files are visible or committed.
- The unauthenticated demo switcher is not exposed publicly.

Technical note for maintainers

The current implementation is described as a Vite-based application with its API running in the Vite process and SQLite for local persistence. Keep the frontend and API running together as documented. Internal paths, database names, and environment variables may retain the legacy WASL name while the visible brand is Qudra.

For persistent issues, record the exact command, full terminal error, Node version, and failed step. Never include API keys or other secrets in bug reports.
